Introduction

2 Project: Optimization

Project: Bootstrap

Introduction

Introduction of Today's Presentation

- Group project 2: Optimization algorithms on a breast cancer diagnosis dataset
 - Build a predictive model based on logistic regression to faciliate cancer diagnosis
 - Compare methods including Newton Raphson, Gradient Decent with general logistic regression and Pathwise Coordinate Descent with regularized logistic regression
- Group project 3: Bootstrapping on developing classification model
 - Build a predictive model based on regularized logistic regression to faciliate down syndrome diagnosis
 - Compare methods including Pathwise Coordinate Descent and smoothed bootstrap estimation

Background Method Result Conclusion

Project: Optimization

Background Method Result Conclusion

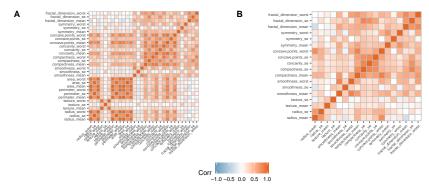

Background

Breast Cancer Data

- The data breast-cancer.csv 33 columns.
 - Covariate "ID" lables individual breast tissue images
 - Covariate "Diagnonsis" indentifies if the image is coming from cancer tissue or benign cases.
 - Mean, standard deviation and the largest values of the distributions of 10 features are computed for the cellnuclei for each case.
- Have 569 row
 - There are 357 benign and 212 malignant cases.

Multicollinearity of the Dataset

- Variable Selection: Reduce multicollinearity based on:
 - o correlation coefficient ≤ 0.7
 - ullet eigenvalue of correlation matrix ≥ 0.01

Background Method Result Conclusion

Method

Logistic Regression Model

Notations

- y: the vector of n response random variable
- X: the $n \times (p+1)$ design matrix (X_i denote the ith row)
- β : the $(p+1) \times 1$ coefficient vector
- Objective function: maximize log-likelihood function

$$\max_{\beta \in \mathbb{R}^{p+1}} \sum_{i=1}^{n} \{ y_i(X_i\beta) - \log(1 + \exp(X_i\beta)) \}$$

• Gradient: $\nabla I(\beta) = X^T(y-p)$, Hessian: $\nabla^2 I(\beta) = -X^T W X$ where $p = \frac{\exp(X\beta)}{1+\exp(X\beta)}$, $W = diag(p_i(1-p_i))$, $i = 1, \cdots, n$. The Hessian is negative definite.

Newton Raphson Algorithm

Newton Raphson with step-halving

$$\beta_{i+1}(\gamma) = \beta_i - \gamma [\nabla^2 I(\beta_i)]^{-1} \nabla I(\beta_i)$$

- Algorithm
 - ullet initilize the estimates denoted as eta_0
 - use the principle of newton raphson to update the estimate, the algorithm of optimizing the step size is
 - Set $\gamma = 1$
 - If $f(\theta_{i+1}(1)) \geq f(\theta_i)$, then set $\theta_{i+1} = \theta_{i+1}(1)$
 - If $f(\theta_{i+1}(1)) \le f(\theta_i)$, search for a value $\gamma \in (0,1)$ for which $f(\theta_{i+1}(\gamma)) \ge f(\theta_i)$, set $\theta_{i+1} = \theta_{i+1}(\gamma)$
 - stop searching until the convergences of the estimates
- Gradient Descent:

$$\beta_{i+1} = \beta_i + H_i \nabla f(\beta_i)$$

LASSO with Pathwise Coordinate Descent

• **Objective function**: maximize the penalized log likelihood with some $\lambda \geq 0$:

$$\min_{\beta \in \mathbb{R}^{p+1}} \left\{ \frac{1}{2n} \sum_{i=1}^{n} (z_i - \sum_{j=0}^{p} x_{i,j} \beta_j)^2 + \lambda P(\beta) \right\}$$

Coordinate-wise descent with weighted update:

$$\tilde{\beta}_{j}^{lasso}(\lambda) \leftarrow \frac{S(\sum_{i=1}^{n} \omega_{i} x_{i,j} (y_{i} - \tilde{y_{i}}^{(-j)}), \lambda)}{\sum_{i=1}^{n} \omega_{i} x_{i,j}^{2}}$$

where
$$\tilde{y_i}^{(-j)} = \sum_{k \neq j} x_{i,k} \tilde{\beta}_k$$
 and $S(\hat{\beta}, \lambda) = sign(\hat{\beta})(|\hat{\beta}| - \lambda)_+$

Logistic-LASSO Model

Object function:

$$\max_{\beta \in \mathbb{R}^{p+1}} \frac{1}{n} \sum_{i=1}^{n} \{ y_i(X_i\beta) - \log(1 + \exp(X_i\beta)) \} - \lambda \sum_{j=0}^{p} |\beta_j|$$

 Quardratic approximation to the negative log likelihood by taylor expansion

$$f(\beta) = -\frac{1}{2n} \sum_{i=1}^{n} w_i (z_i - \sum_{i=0}^{p} x_{i,j} \beta_j)^2 + C(\tilde{\beta})$$

where

$$z_i = \tilde{\beta}_0 + x_i^T \tilde{\beta} + \frac{y_i - \tilde{p}(x_i)}{\tilde{p}(x_i)(1 - \tilde{p}(x_i))}$$
, working response $w_i = \tilde{p}(x_i)(1 - \tilde{p}(x_i))$, working weights

Logistic-LASSO Model with Pathwise Coordinate Descent Algorithm

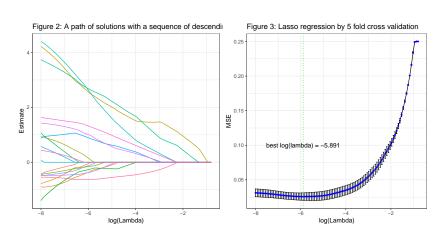

Algorithm

- outer loop: start with λ that all the coefficients are forced to be zerp, then decrement λ ;
- middle loop: update the quardratic $f(\beta)$ using the current estimates of parameters;
- inner loop: run the coordinate descent algorithm on the penalized weighted least square problem.

^a Dataset: Breast Cancer Diagnosis

Background Method Result Conclusion

Conclusion

Conclusion and Discussion

- The results of our methods are consistent to the estimation from R's built-in packages
 - Newton-Raphson has the convincing estimation and it converged quickly
 - Gradient decent method showed similar estimation as Newton-Raphson method but it was less efficient
 - For logistic lasso, according to the result of 5-fold cross validation and estimation result, the λ with the lowest MSE and it shrunk six parameters to zero, which is comparable to the result by R's built-in packages.
- Prediction capability of logistic regression and penalized logistic regression are similar

ackground lethod esult onclusion

Project: Bootstrap

Background Method Result Conclusion

Background

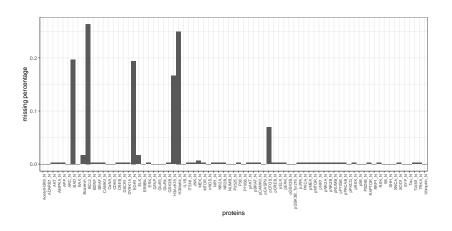

Down Syndrome Data

- The data Down.csv has 1080 rows and 79 columns
 - MouseID identifies individual mice
 - 2-78 are the expression levels of 77 proteins/protein modifications that produced detectable signals in the nuclear fraction of cortex.
 - Column 79 indicates whether the mouse is a control or has Down syndrome.
- The goal is to develop classification model based on the proteins expression levels.

Missingness of the Dataset

- Variable Selection:
 - Delete variables with high missing rate ($\geq 15\%$)
 - ullet For those covariates with missing rate < 15%, we assumed them to be missing completely at random(MCAR)
- Regularized method is applied due to the intrinsic correlation between individual proteins

Missingness Plot

Background Method Result Conclusion

Method

Eestimation Methods with Regularized Logistic Regression

- Pathwise Coordinate Descent Algorithm based on the dataset
- Smoothed Bootstrap
 - ullet We define lasso logistic regression models with different λs are considered different models. All models are wrong
 - idea of Bagging: average the model estimators
 - bootstrap data from the original dataset
 - ullet cross validation and select the best λ_i^* for each repetition
 - calculate average $\lambda^* = \frac{1}{B} \sum_{i=1}^{B} \lambda_i^*$

Smoothed Bootstrap Estimation and Inference

- Point estimation
 - for each bootstrap, get the best model and estimate $t(y^*)$
 - smooth $\hat{\mu} = t(y)$ by averaging over replications, defining

$$\tilde{\mu} = s(y) = \frac{1}{B} \sum_{i=1}^{B} t(y^*)$$

• Inference: the nonparametric delta-method estimate of se:

$$\tilde{sd}_B = \left[\sum_{i=1}^n c\hat{o}v_j^2\right]^{1/2}$$

where

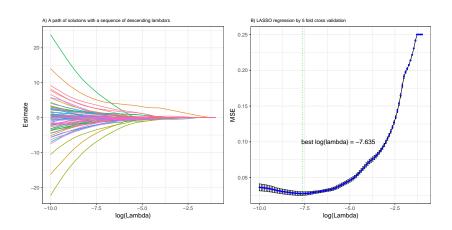

$$c\hat{o}v_j = \sum_{i=1}^{B} (Y_{ij}^* - Y_{.j}^*)(t_i^* - t_.^*)/B$$

with
$$Y_{i}^* = \sum_{i=1}^B Y_{ii}^* / B$$
 and $t_i^* = \sum_{i=1}^B t_i^* / B = s(y)$.

Background Method Result Conclusion

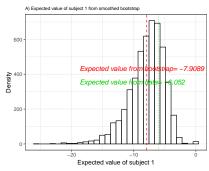

Result

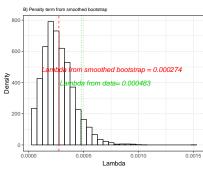

Pathwise Coordinate Descent with Logistic-LASSO

Logistic-LASSO with Smooth Bootstrap

Discrepancy between results of LASSO with PCD and smoothed bootstrap estimation in both prediction and finding the best λ , the PCD is deviated from the center of empirical distribution.

Cross Validation for Model Prediction Comparison

We used 10 fold cross-validation to compare two models: - one is with λ selected from data - the other is selected by smoothed bootstrap

Table 2: The comparison of performance for two models

	Misclassification rate	Mean squred error	
Penalty chosen by data	0.0353	0.0229	
Penalty selected from smoothed bootstrap	0.0335	0.0216	

^a Dataset: Proteins expression levels of Down syndrome

Significant Proteins Selection by Smooth Bootstrap Estimation

Our identification criterions are:

- selected probability: the probability of certain protein selected during the bootstrap
 - the chosen probability greater than 96%
- confidence interval:
 - percentile confidence interval by using quantile function of the bootstrap empirical distribution
 - smoothed confidence interval calculated as proposed $\tilde{\mu} \pm 1.96 \cdot \tilde{sd}_B$
 - both CI exclude zero

Based on that, we got 27 proteins that meets these two criterions.

Significant Proteins with Bootstap n=5000

Background Method Result Conclusion

Conclusion

Conclusion and Discussion

- We applied two methods to get estimates for Penalized Logistic Lasso Regression: Pathwise Coordinate Descent Estimation and Smoothed Bootstrap to select the best λ .
 - cross validation result showed similar accuracy in prediction.
 - classical statistical theory does ignore the model selection process in assessing estimation accuracy, which is consistant with the Efron paper results.
- We conducted inference based on Smoothed Bootstrap Estimation, and identified 27 proteins that are significantly associated with the Down syndrome.
